- តំលៃសង្ឃឹម $E(X) = n$ និង វ៉ារ្យ៉ង់ $V(X) = 2n$

- Gamma Function $\Gamma(t) = \displaystyle\int_0^\infty x^{t-1}e^{-x}dx; \quad t > 0$

សម្គាល់ ៤. *What does degree of freedom(df) mean ?*

- *We have been treating degrees of freedom as simply a parameter in the chi-square distribution. In fact, it has a very important interpretation, and measures the number of independent variables in the expression being measured. A more rigorous mathematical discussion would equate the independent variables with vectors in a vector space, but in this exposition we shall simply relate the important characteristics that result.*

- *In the quantity $(x_i - \bar{x})^2$, the sample mean was actually the sum of the n data values x_i. If we know the value of $\bar{x}$ and begin examining our sample, once we have measured $n-1$ of the data values x_i, we will automatically know the last value. Specifically, we have $x_n = \bar{x} - \sum_{i=1}^{n-1} x_i$. The last value, x_n, is not free to vary. Therefore the quantity $\sum_{i=1}^{n}(x_i - \bar{x})^2$ has $n-1$ degrees of freedom.*

- *The quantity $(x_i - \mu)^2$ behaves differently. The data values x_i are from a sample, but μ describes the population mean. Knowing μ and $n-1$ values of x_i does not force a particular value of x_n. The last value x_n is still free to vary. Therefore, the quantity $\sum_{i=1}^{n}(x_i - \mu)^2$ has n degrees of freedom.*

- *And in the quantity $(x_i - \mu)^2$, knowing the value of μ will not tell us anything about the value of $\bar{x}$. Therefore, the quantity $\bar{x}$ is free to vary. This mathematical expression does not explicitly depend on knowledge of particular data values, so there is only one unknown quantity, $\bar{x}$, that needs to be determined. This expression has one degree of freedom.*
